

# **Post Transplant Lymphoproliferative disorder – An update**

**Dr Paul Fields**

**Department of Haematology**

**Guys and St Thomas NHS Trust**

**15/03/18**

## **Definition of PTLD**

Are lymphomas that occur after solid organ (up to 10%) or stem cell transplantation

Cause by a proliferation of lymphoid tissue

It is most common form of post transplant malignancy in children and in adults 2<sup>nd</sup> most common after skin Cancer

In children and adults common cause of cancer related mortality after solid organ transplantation and reported overall mortality often exceeds 50%

In Europe and US 85% are B cell lineage and most > 80% are associated with EBV infection.

Around 10-15% of PTLD are of T cell lineage around 30% which are associated with EBV

## Incidence PTLD : Adult and Paediatric

	Adult %	Paediatric %
<b>Renal</b>	1-2.3	1.2-10
<b>Liver</b>	1-2.8	4-15
<b>Heart</b>	1-6.3	6.4-19.5
<b>Heart Lung</b>	2.4-5.8	
<b>Lung</b>	4.2-10	
<b>Small Bowel</b>	20	

Risk higher in Children – higher incidence of EBV  
Transplanted organ or bone marrow may contain EBV  
Infected cells , EBV infection very common

***Taylor et al Cr Review Oncology  
Haematology 2005***

## Comparison of SOT-PTLD and HSCT-PTLD

Transplant population	Incidence	Timing of PTLD development	EBV demonstrated in tumour	PTLD origin	Prognosis	Specific risk factors
SOT-PTLD	1–20% depending on the organ	Bimodal	Frequently EBV-positive	<b>Recipient</b>	Variable	EBV seromismatch, very young or very old recipients
HSCT-PTLD	<2%	Mainly early-onset	Mainly EBV-positive	<b>Donor</b>	Variable	EBV seromismatch, higher grades of graft-versus-host disease, pre-transplant splenectomy

## **Classified into 4 types**

1. Early lesion – which normally regress if immune suppression reduced
2. Polymorphic PTLD ( P-PTLD) lesions which contain a mixture of different types of cells
3. Monomorphic ( M-PTLD) : which contains 1 type of cell and is the most common type of PTLD

It is usually a Non Hodgkin Lymphoma- Morphologically Diffuse Large B cell lymphoma is the most common type of M-PTLD, but occasionally other types such as Burkitt lymphoma and other rarer types can occur ( such as T NHL)

4. Classical Hodgkin lymphoma type – which is very rare

## Histopathological markers for PTLD

**a** | CD20-positive stain in monomorphic post-transplant lymphoproliferative disease (PTLD).

**b** | Epstein–Barr virus (EBV)-encoded RNA (EBER)-positive stain in monomorphic PTLD.

**c** | Immunostaining for CD30 shows both cytoplasmic and Golgi staining characteristic of Reed–Sternberg cells in Hodgkin PTLD.

**d** | Immunostaining for CD15 shows its presence in the Reed–Sternberg cells in Hodgkin PTLD.

## **Clinical features**

Highly variable presentation : requires high index of clinical suspicion

50% fever, 30% lymphadenopathy (solitary or multiple)

Non specific symptoms such as tonsillitis (more in children) and weight loss / abdominal symptoms

15% emergency surgical presentation – intestinal perforation often small / large bowel

Small group fulminant presentation – disseminated disease / systemic symptoms

CNS involved into 30% of PTLN and in many of these cases the disease maybe confined to the CNS

## **Diagnosis**

Histological examination of biopsy tissue

Excision is preferable to incision needle

FNA is not adequate

## **Histology**

Presence of EBV by IHC and FISH

Cellular infiltrates with IHC CD Ag staining

Staging as for conventional NHL

## **Imaging**

CT – C/A/P/N

PET/CT – (preferred method – excellent for extranodal disease )

## **Markers**

IHC : Ki- 67, Ig Heavy chains, CD 10 , BCL 2 , BCL 6, Cyclin D1, CD21 , CD23, CD38 , IRF4/MUM-1, PAX 5

EBV : EBV – LMP-1 or EBER ISH (if EBV LMP 1 negative , EBER ISH is recommended)

Molecular : Ig and TCR gene re arrangements

Further tests in certain circumstances

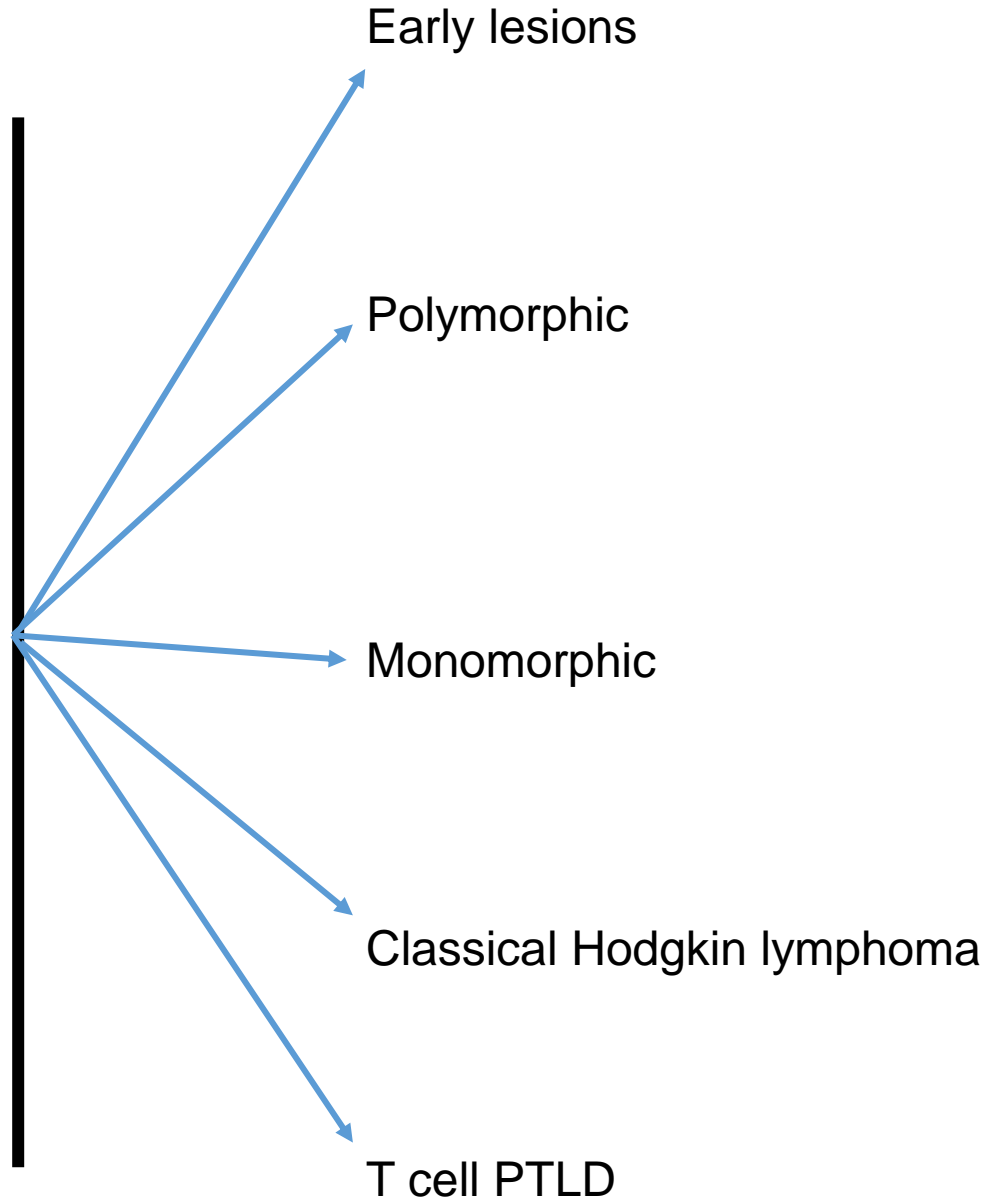

To reveal definitive histological subtype

## Clinical work up

PS  
LDH, U&Es, Creatinine  
FBC differential  
Hep B testing  
C/A/P CT  
Full body PET/CT

## Further

Echocardiogram / MUGA  
Bone marrow exam  
Brain MRI with / without Contrast  
EBV serology : Primary versus reactivation  
EBV PCR  
CMV PCR

## Typical case

2004

1 stone weight loss ,  
change in BH

Central / upper abdominal pain 5/52

I/S : FK506 3mg bd

Azathioprine 150mg od

**Jejunal biopsy**

**No evidence of Carcinoma**

**High power**

## Immunohistochemistry

**CD20**

**CD79a**

**Mib-1**

**EBER**

**Final diagnosis = DLBCL [EBV -ve]**

## **Subsequent joint follow up management ::: Renal and Haematology**

Treatment commenced with R-CHOP

6 Further cycles well tolerated

Repeat interim CT –PET complete response

End of treatment scan CMR

# **Pathogenesis**

# Life cycle of EBV infection to PTLD development

Nature Reviews | Disease Primers

EBV enters submucosal cells  
 ↓  
 Viral gene expression induced  
 ↓  
 B cell blasts kept in check by host CTLs  
 ↓  
 Immune suppression : ↓ CTL  
 ↓  
 PTLD development

# Immune response triggered by latently infected B cells with or without immunosuppression

## Normal response

EBV Ag expression : LMP1, 2A, EBNA

Infected cell recognised by host CD4/ CD8

Apoptosis induced via FAS/FASL ( Caspase 8 mediated )

## Transplant scenario

I/S : Blunt immune response

EBV cell + IL-6 autocrine growth factor . IL-10 suppress Antiviral activity

Exhaustion via PDL-1 , PD-1

c FLIP – homologue of caspase 8 –disrupts activation

Nature Reviews | Disease Primers

**Schematic diagram of EBV-mediated oncogenic signalling pathway activation in EBV-positive diffuse large B-cell lymphoma of the elderly.**

Chi Young Ok et al. Blood 2013;122:328-340

**Treatment**

## **Options**

Reduced immune suppression

Immunotherapy – Single Agent Rituximab

Chemotherapy agents

Radiotherapy

Surgery – often required for fulminant emergency presentation , excision and assessment for  
Further adjuvant therapies above

Future : Novel agents

# **European PTLD trials**

**Dr R Trappe, Dr S Choquet**

**(Germany/France)**

# Results

## **PTLD-1 :**

70 Patients – trial examined use of single agent 4 x R followed by R-CHOP

ORR 60% after rituximab alone (20% CR)

90% after R-CHOP

Median PFS 4 years

Median OS 6.6 years

Treatment related mortality 10.6%

## **PTLD-2 :**

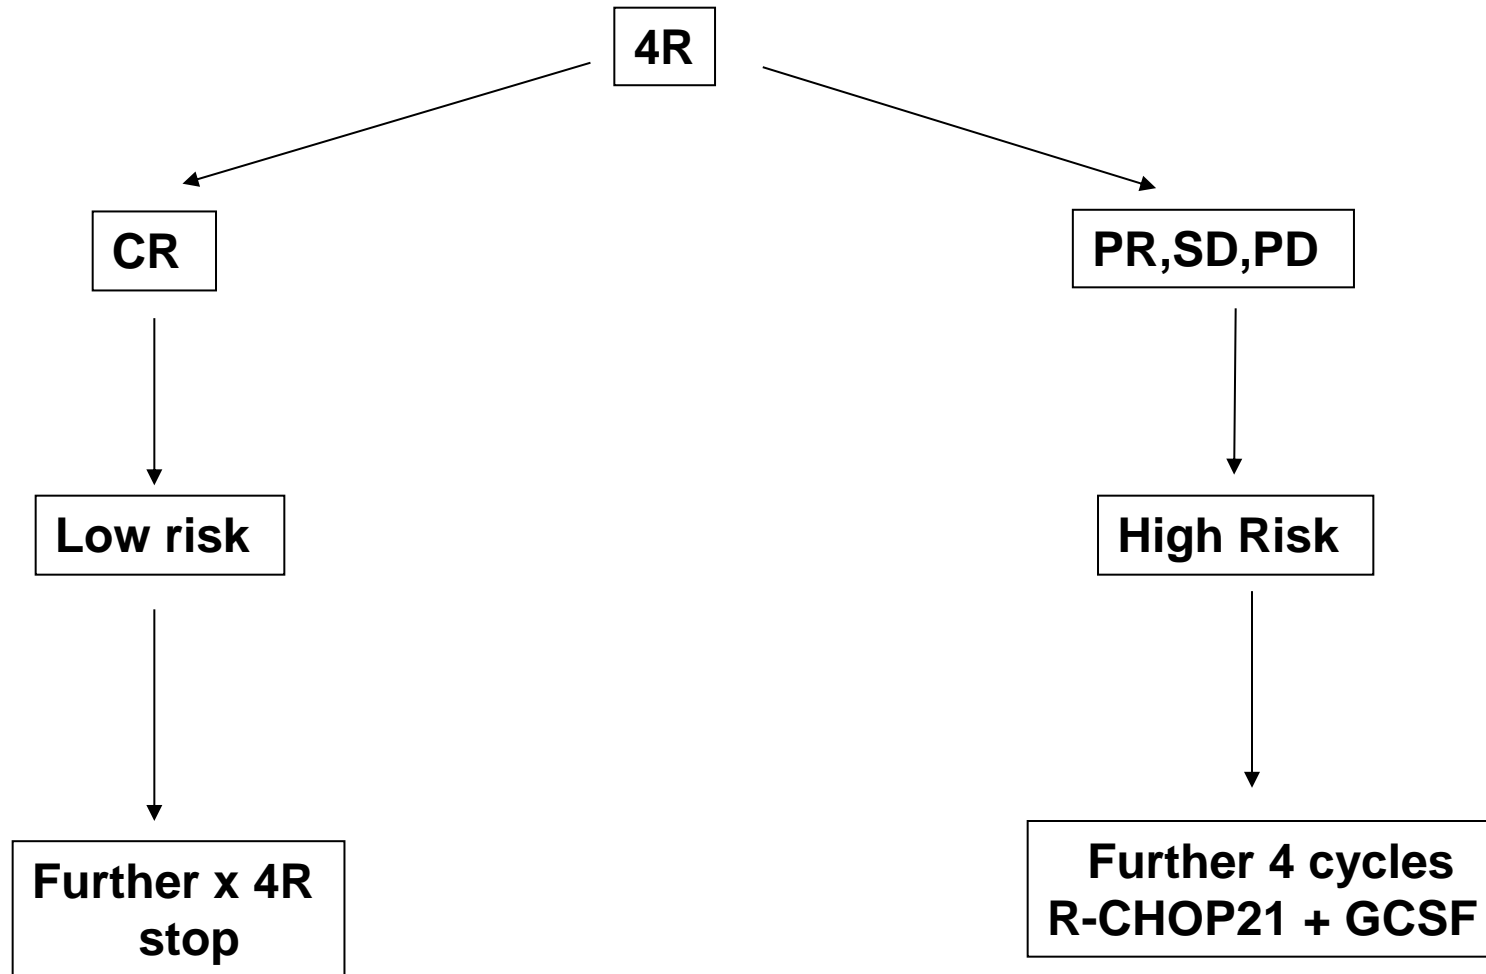

Patients who received rituximab monotherapy and achieved CR – amendment made so patients received 4 further injections rituximab injections every 3 weeks and stopped (so 8 injections in total alone)

If the response was incomplete patients received 4 cycles of R-CHOP,

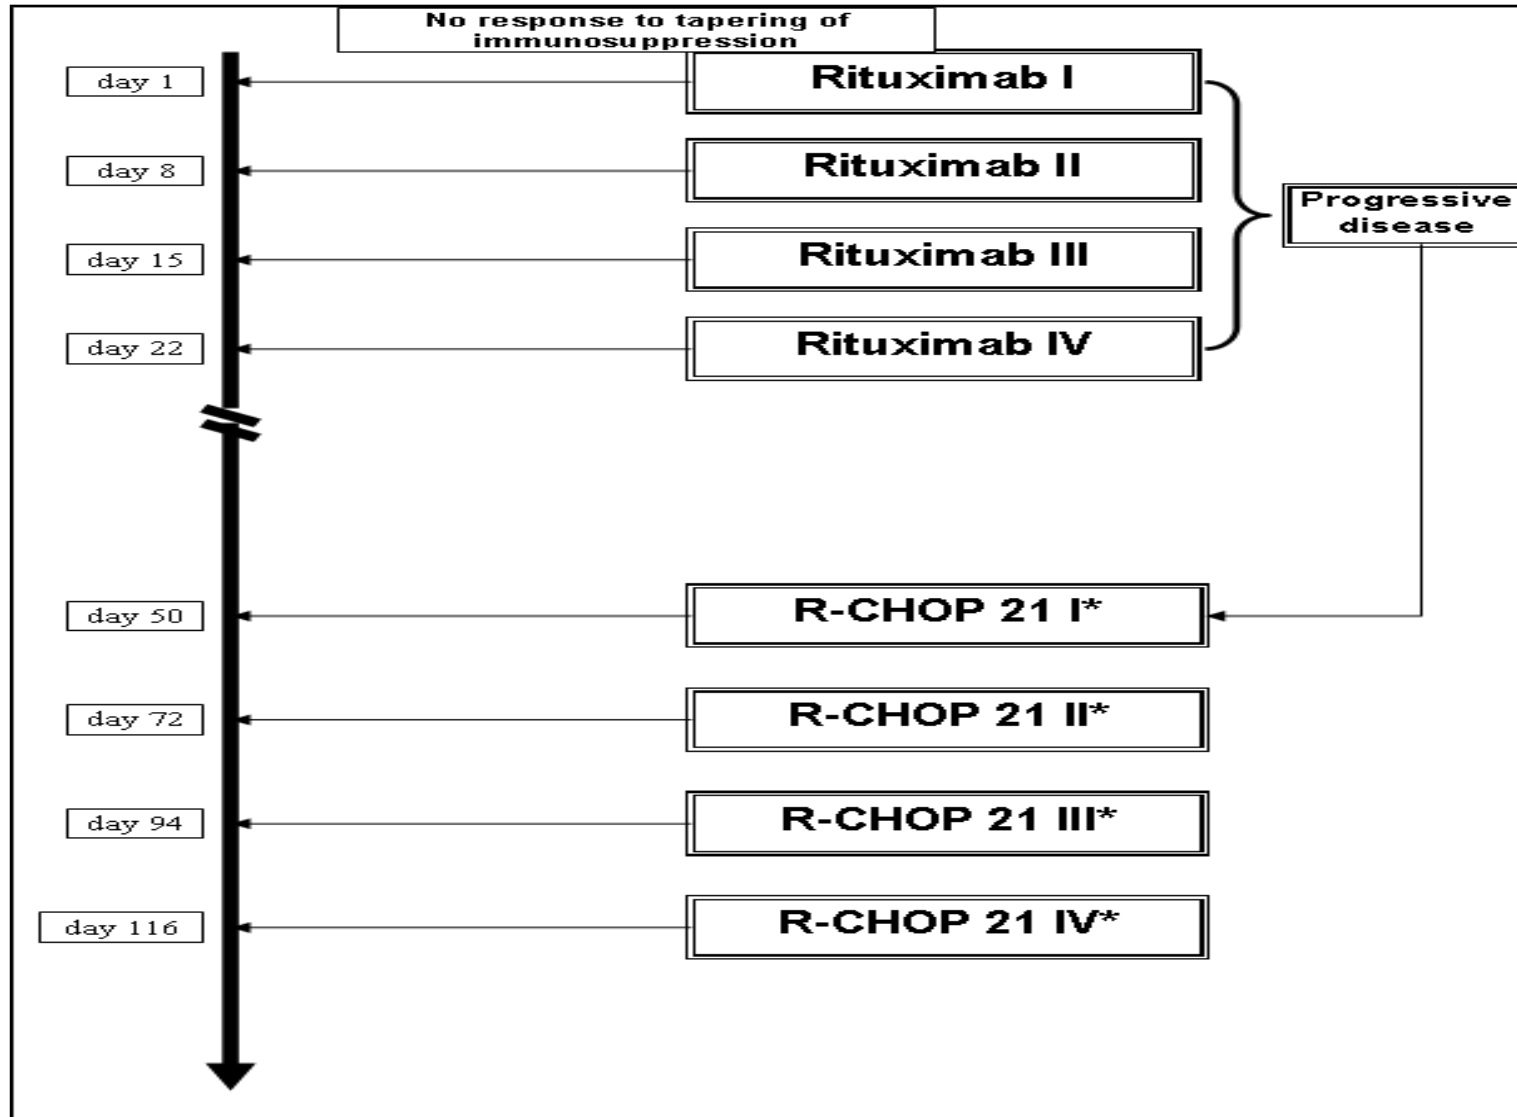

The results published in abstract form (ASH 2016) show similar results CR to 4R + 4- R-CHOP but lower toxicity

= termed “sequential treatment”

# Trial Schema : response adapted approach

# PTLD-1, PTLD-2

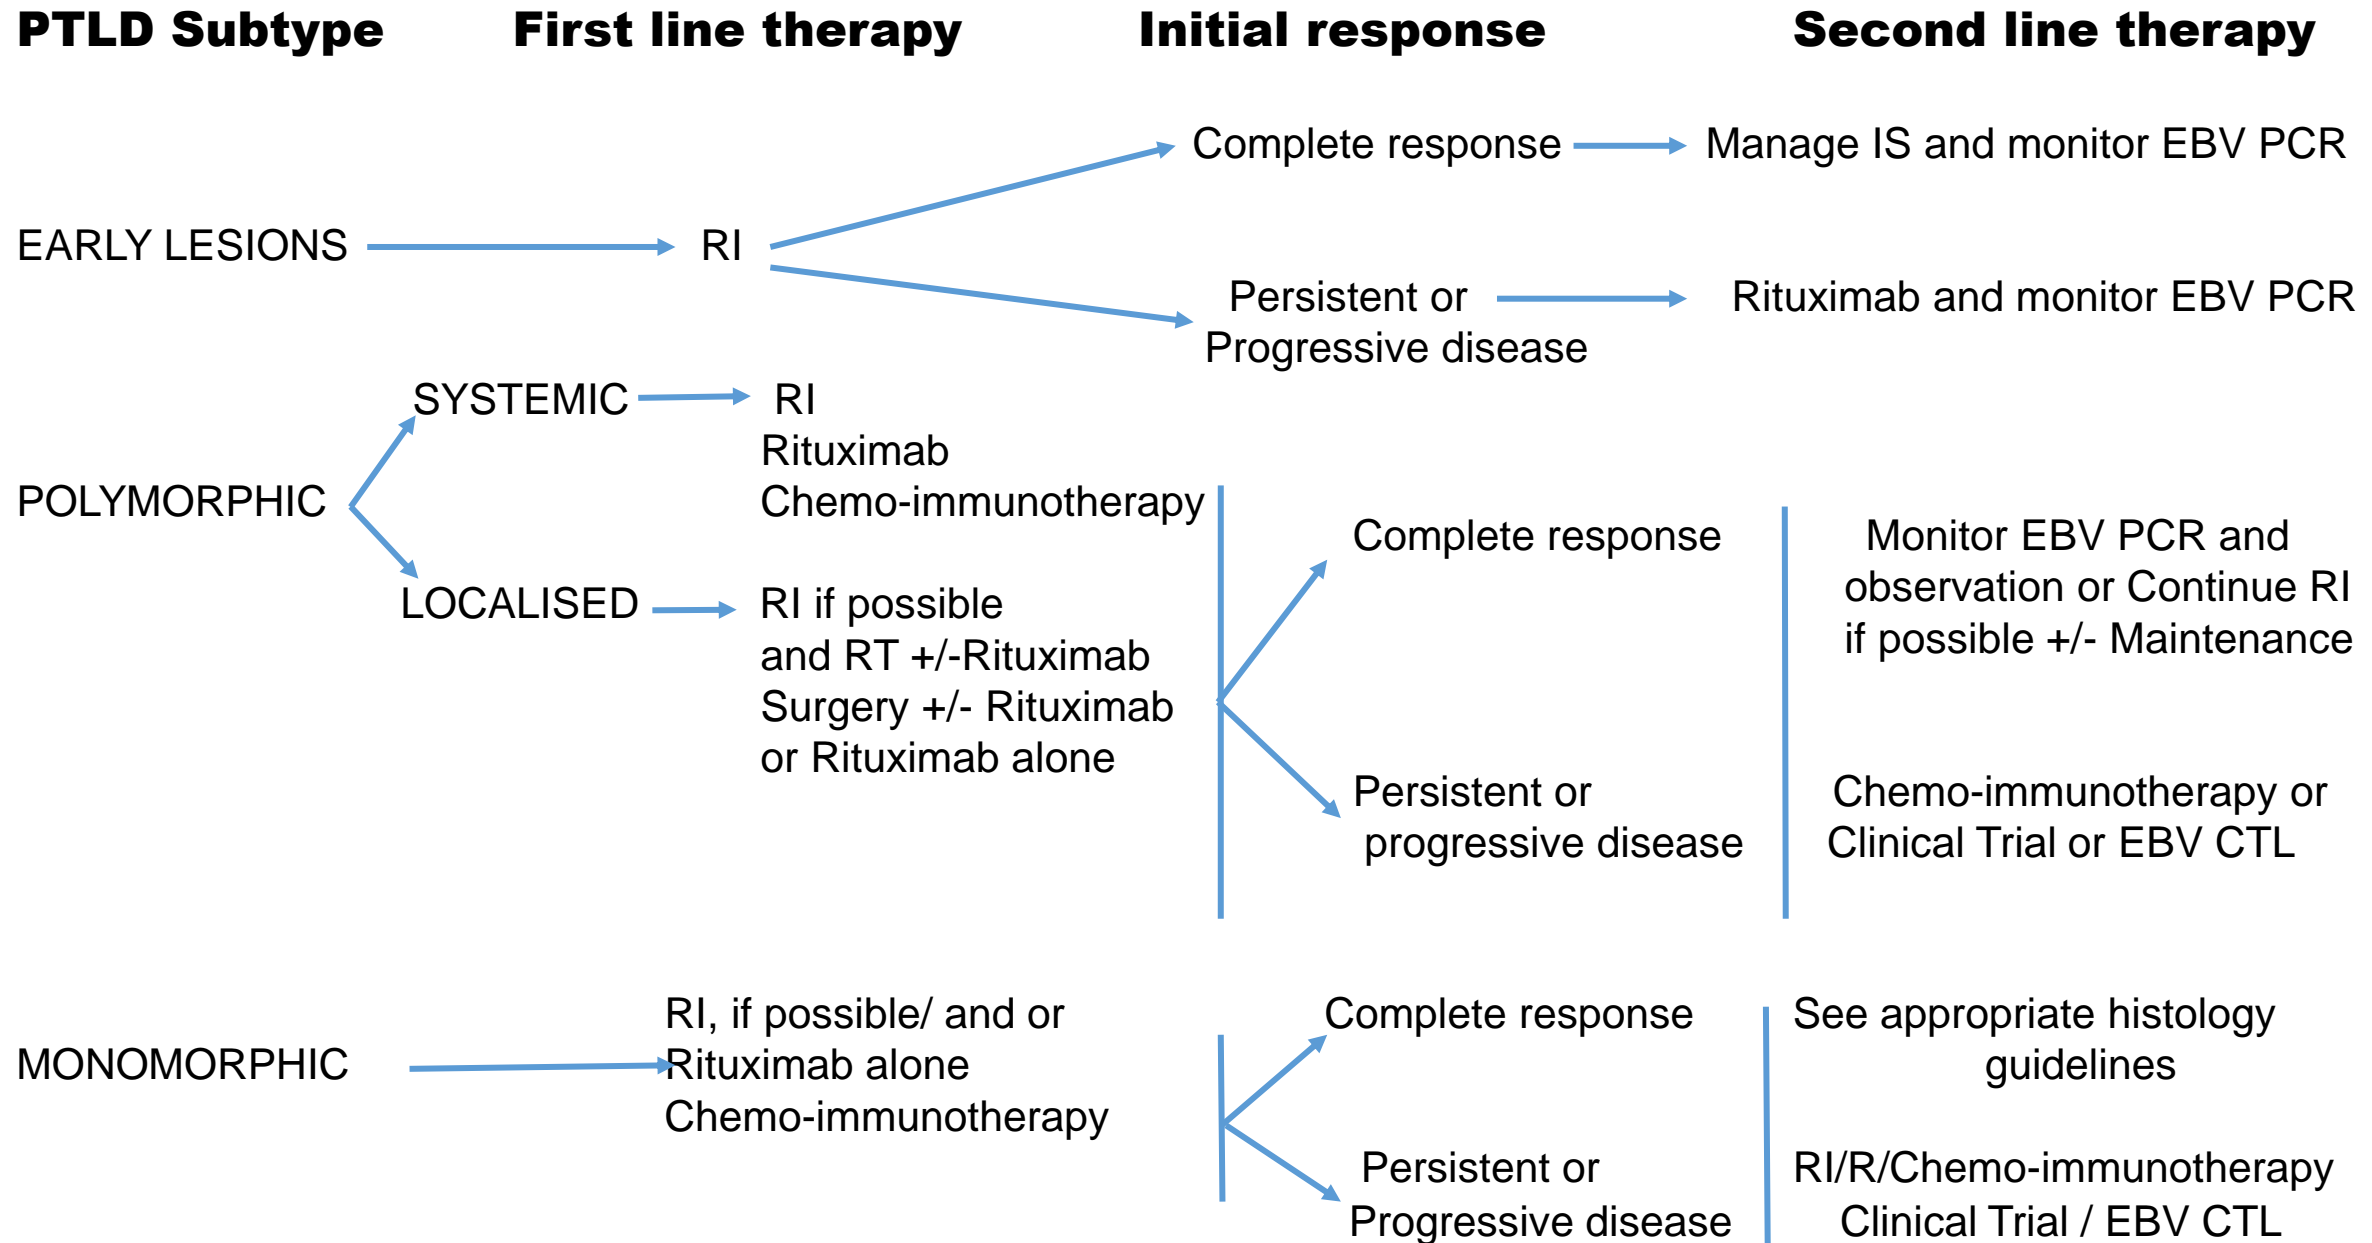

Patients with a complete remission at day 50 will not receive chemotherapy and will go on with rituximab (R) single agent (8 injections in total)

**Establishing the concept of “response adapted approach”**

# Current PTLD Management approach

## **Treatment Regimens**

### **Sequential chemo-immunotherapy**

Rituximab 375 mg/m<sup>2</sup> x 4 weeks

#### Restage with PET/CT

- If PET/CT scan negative , rituximab 375mg/m<sup>2</sup> every 3/52 x 4 cycles
- If PET/CT scan positive, CHOP 21 every 3 weeks x 4cycles  
Prophylaxis for tumour lysis syndrome

### **Concurrent immuno-therapy**

R-CHOP (rituximab , cyclophosphamide, doxorubicin, vincristine, prednisolone)

For frail patients :

R-CVP

R-CEPP

R-CEOP

# PTLD in adults after SOT: What to do? a treatment algorithm

Primary EBV infection-associated PTLD	EBV-associated PTLD with EBV-reactivation and non EBV-associated PTLD								
Antiviral treatment + IR	Immunosuppression reduction (IR)								
	CD20-positive PTLD				CD20-negative PTLD				
	wait for response to IR				wait for response to IR				
Early lesion- ... DLBCL-type PTLD	Early lesion-	Poly-morphic PTLD	... DLBCL-type- ... PTLD	Burkitt-PTLD	pCNS PTLD	Plasmocytoma-like- and Hodgkin-PTLD	Plasmablastic- and T-cell PTLD		
no CR	Ann Arbor stage I	Ann Arbor stage II-IV		Ann Arbor any stage		Ann Arbor stage I	Ann Arbor stage II-IV	Ann Arbor any stage	
IVIG*	4 courses rituximab (R)	<b>Sequential treatment (ST):</b>  4 courses rituximab (R) followed by 4 cycles of CHOP-21 + GCSF in fixed sequence <sup>++</sup>			4xR plus HD-MTX*	<b>radio-therapy</b>  for plasmocytoma-like PTLD: also surgical resection	4# PAD or ABVD + GCSF	6-8 cycles CHOP-21 + GCSF <sup>‡</sup>	
no CR	no CR <sup>†</sup>				or		4xR plus WBRT*		(if response but no CR after 4 cycles: additional cycles)
4 courses rituximab*	surgical resection / radiotherapy  +/- 4 additional courses R								

# Rituximab monotherapy

Serial FDG-PET/CT scans are shown from a patient presenting with a massive abdominal localization of a Burkitt non-Hodgkin post-transplant lymphoproliferative disease (PTLD) (part a)

After four weekly injections of rituximab, a complete response was obtained (part b)

The patient received 4 more rituximab injections at 21-day intervals. At the last evaluation, 5 years later, complete response was maintained (part c)

# Sequential therapy

**PTLD : DLBCL abdominal**

**Post 4 x R weekly : PR**

**4 Further R-CHOP : CMR**

Nature Reviews | **Disease Primers**

Maximum-intensity projection 18F-FDG–PET/CT images.

Baseline

Interim PET

## Maximum-intensity projection $^{18}\text{F}$ -FDG–PET/CT images

Baseline image showed multiple supra- and infradiaphragmatic nodal lesions and extranodal lesions in breast, intestines, and bone marrow (left);

$^{18}\text{F}$ -FDG–PET/CT after 4 cycles of therapy showed a complete metabolic response in all nodal and extranodal lesions, with the exception of limited residual hypermetabolic lesions in the intestinal tract adjacent to the kidney transplant in the right iliac fossa (right).

**Future : Use of targeted agents**

## **“TIDAL” study**

### **Risk-stratified sequential Treatment with Ibrutinib and Rituximab (IR) and IR-CHOP for De-novo post-transplant Lymphoproliferative disorder (PTLD) : CI : Dr T Manne : Newcastle**

Trial Design : This is a prospective, phase 2, single arm trial evaluating the addition of ibrutinib to rituximab (IR) therapy in patients diagnosed with PTLD.

Patients will receive IR combination therapy for seven weeks, after which they will receive IR (if categorised as low risk) or IR-CHOP chemotherapy (if categorised as high risk).

#### **Objectives**

Primary objective : The primary objective is to evaluate complete remission (CR) after seven weeks of therapy.

Secondary objectives : The secondary objectives are to evaluate response, event-free survival (EFS), overall survival (OS), progression-free survival (PFS), treatment-related mortality, frequency of grade III and IV leucocytopenia and grade III and IV infections and patients entering into low and high risk arms after IR therapy.

## Mechanism of action of Ibrutinib – BTK inhibitor

# TIDAL trial Schema

Patient Consent

Eligibility checked (PET/CT/MUGA)

Rituximab on Day 1,8,15 and 22  
Ibrutinib D1-49

Low Risk

High Risk

Four 3 weekly cycles of Rituximab on D50,71,92,113 + Ibrutinib on Days 50-133

Four 3 Weekly cycles of R-CHOP on D 50,71,92,113  
Ibrutinib on D50—133

Response assessment : PET/CT around D155  
(6 post Rituximab treatment )

Patients followed up every 4/12 for 2 years  
CT scan at 12 months

**Low Risk** : Either CR or PR with initial IPI 0-1

**High Risk** : PR with an initial IPI 2-5 or stable or progressive disease

If at any time point clinical progressive disease is identified during initial IR therapy go to straight to high risk arm

## **Inclusion criteria**

- Untreated CD20 positive PTLD with or without EBV association , biopsy positive  
upfront reduction of immune suppression with or without anti viral therapy is permissible
- PTLD with meningeal or CNS involvement can be included
- Clinically insufficient response to upfront RI
- Plts > 100 or > 50 if BM + ve , ANC > 1 , independent of GCF
- CrCl  $\geq$  30 ml/min , AST or ALT  $\leq$  3 ULN , Bilirubin  $\leq$  1.5 ULN
- PTT / APPT  $\leq$  1.2 ULN
- LVEF > 50%
- ECOG  $\leq$  2 , Age > 16

## **Conclusions / Future perspectives**

Response adapted approach according to risk internationally adopted, has improved results

Integrating national registries prospectively – mandatory reporting of PTLD in all transplant trials, better capture of data

Identifying new risk factors – better assessment/ surrogates for immune suppression load and association with PTLD risk , with HLA association and Non EBV

Refining WHO 2008 classification to include impact of EBV (negative,positive,latency type,lytic activation) stromal microenvironment, molecular findings

Better preventive strategies (e.g. EBV PCR , cytokine gene polymorphisms )

Drive to create international cooperation and inclusion of patients in prospective international trials

Enhanced risk adapted strategies to pick our poor risk

Better biological understanding EBV –ve cases ; why in EBV + cases primary infection carries a higher risk of PTLD versus reactivation infection
